Chemical evolution

What observation tell us?

Supernovae

OISTER

- **Observables:**
light curve, spectrum, polarization
- **Pros:**
Nucleosynthesis in a single SN can be measured
- **Cons:**
Abundance of only major elements (O, Si) is available
- Only for SNe in the **nearby** Universe

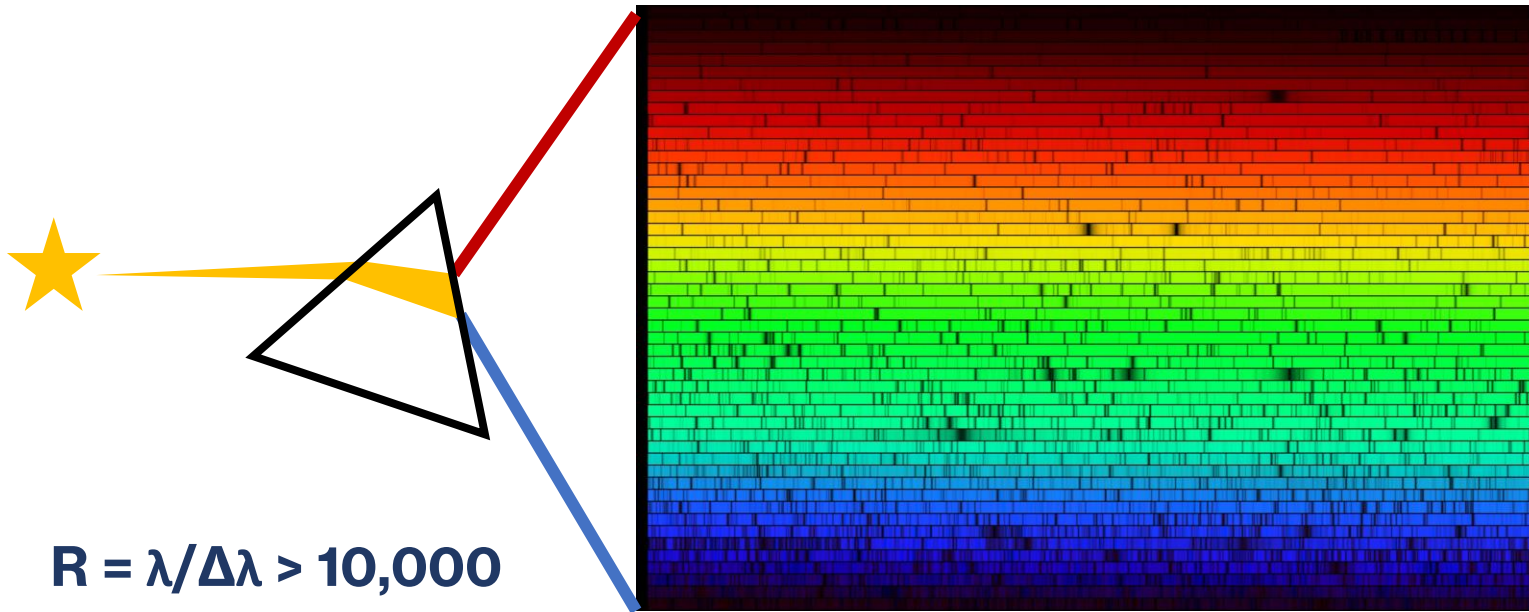

Metal-poor stars

- **Observables:**
spectrum
- **Pros:**
Detailed abundance including minor elements can be measured
- **Cons:**
It can be a superposition of multiple SNe
- Only for SNe in the **early** Universe

The detailed abundances in metal-poor stars are **complementary** with the transient observation by multi-messenger astronomy.

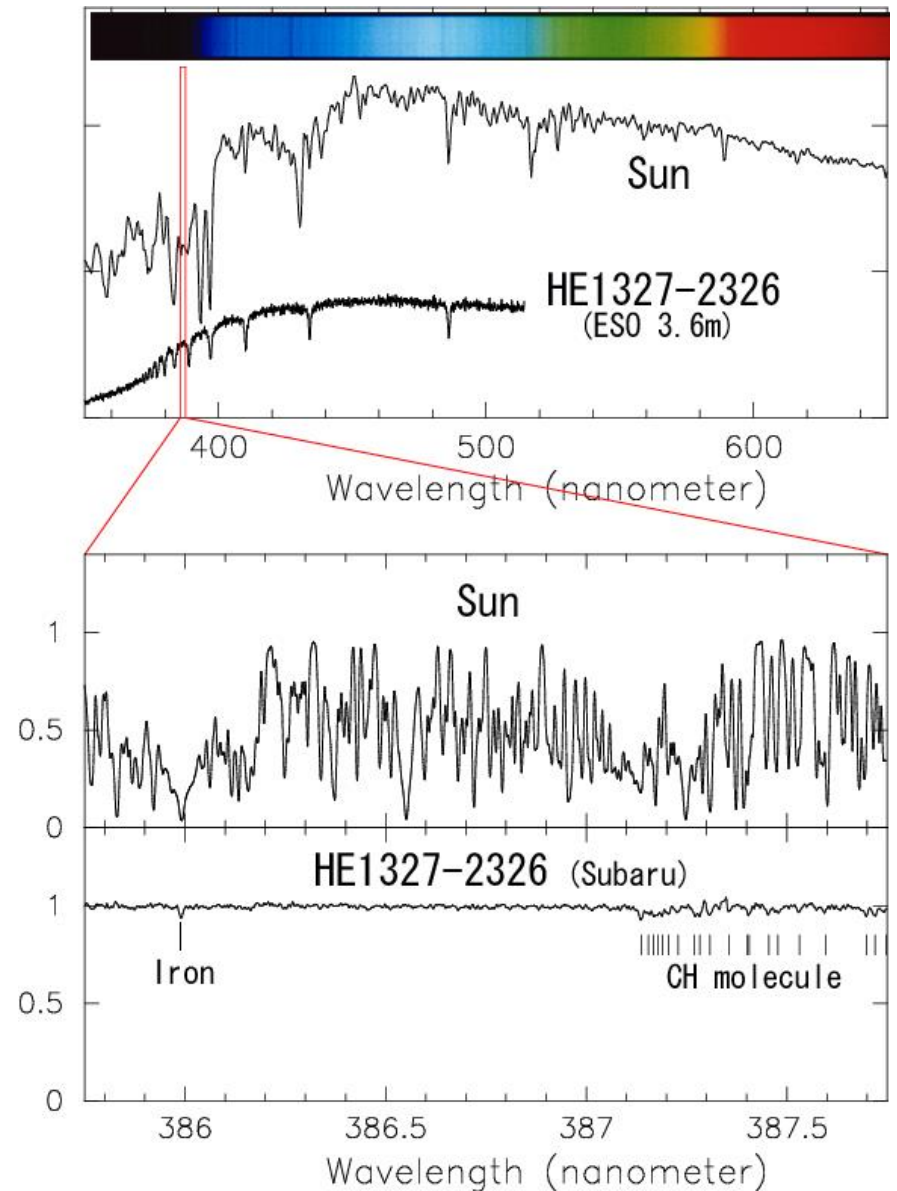

High-resolution spectroscopy

The detailed abundances in stars are measured by high-resolution spectroscopy.

The high-resolution spectroscopy distributing the photons to large number ($> 10,000$) of parts is only possible for **bright objects**.

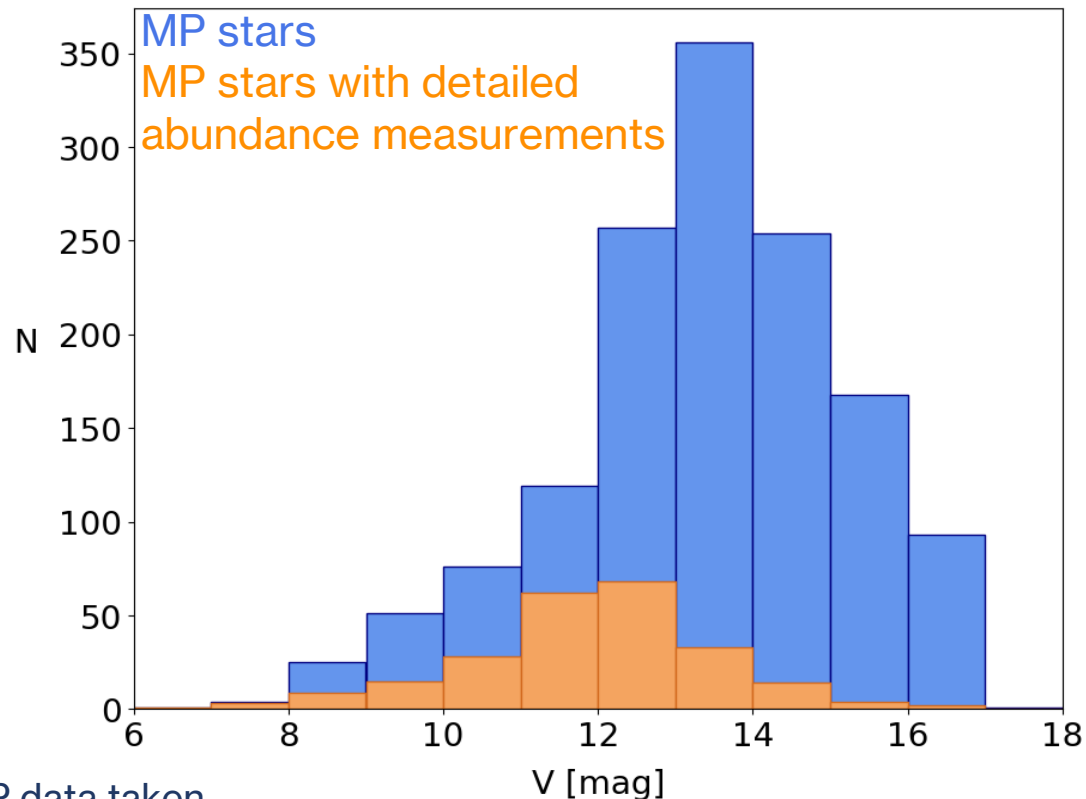

© Subaru Telescope

Importance of bright metal-poor stars

Bright metal-poor stars enable

- ① Measurement of **rare elements** such as r-process elements (Furutsuka-san's talk)
- ② Measurement of **low abundance** or **stringent upper limit**

Detailed abundances are available for MP stars ($[\text{Fe}/\text{H}] < -2$) with $V < 12$, but they are still rare.

Wide (and shallow) survey is required to increase them.

Survey method: narrow-band photometry

Starckenburg et al. (2017)

Pristine survey w/ CFHT (4 m)

SkyMapper survey w/ SkyMapper (1.3 m)

Stars with lower metallicity have weaker CaHK lines and are located at the left top side in color-color diagram.

Northern-sky survey for bright metal-poor stars

Aims:

- Precise measurements of rare elements
- Understanding of the nature of first stars and the origin of element

Survey design

STEP 01

Kiso (1.05 m)

Survey

- Narrow-band photometry with Tomo-e Gozen
- Select bright MP candidates with $[Fe/H] < -2$

STEP 02

Nayuta (2 m)

Metallicity estimation

- Medium-res. Spectroscopy with MALLS
- $R \sim 7500$
- Opt. (4900-5300Å)
- Metallicity(Fe) and α (Mg) abundance

STEP 03

Seimei (3.8 m)

Abundance determination

- High-res. spectroscopy with GAOES-RV
- $R \sim 65000$
- Opt. (5160-5930 Å)
- Individual elements (Mg, Ca, Sc, Ti, Cr, Fe, Ni, Ba)

STEP 04

Subaru (8 m)

Detailed abundance determination

- High-res. spectroscopy with HDS
- $R > 45000$
- Opt. and UV
- Individual elements incl. rare elements

Survey status

Okada et al. in prep.

Follow-ups of MP candidates

Okada et al. in prep.

Status and Future plan

Okada et al. in prep.

Summary

The detailed abundance available only in metal-poor stars provides unique information on the origin of element, being complementary with the multi-messenger astronomy.

Search for bright MP stars to measure detailed chemical compositions is ongoing

Okada et al. in prep.
